## Abstract of the Disclosure

An internal voltage generator for performing the restoration of an output voltage to a target value despite variance of an internal voltage includes a reference voltage divider that generates first and second reference voltages, and a first differential amplifier that receives the first reference voltage from reference voltage divider through a first input terminal of first differential amplifier and generates a first differential signal. A second differential amplifier receives the second reference voltage from the reference voltage divider through a first input terminal of second: differential amplifier and generates differential signal. A voltage source driver is driven by the first and second differential signals from first and second differential amplifiers, respectively, and provides a driver voltage within a desired and adjustable range.
